

Liquid UI – linerecordsplit Command

Process:

The linerecordsplit command is used to break up a long string into its component parts based on the parameters.

Syntax:

```
var elementArr = linerecordsplit(z_string, [{"label":"Name1", "length":10}, {"label":"Name2", "length":20}]);
```

label: the label is always paired with a length. Together, they identify the split parts of the string.

length: length specifies the length to split from the string and it is always paired with label.

You can either use a single entry format or an array.

Below are the Possible syntaxes

Single entry:

```
{"label":"Name1","length":20}
```

Array:

```
[{"label":"NAME1", "length":20}, {"label":"NAME2", "length":10}]
```

LiquidUI Script:

```
////////// SAPLSMTR_NAVIGATION.E0100.sjs //////////
```

```
var z_string = "0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZ";
```

```
var elementArr = linerecordsplit(z_string, [{"label":"NUMBERS", "length":10}, {"label":"ALPHABETS", "length":20}]);
```

```
println("label NUMBERS is "+elementArr.NUMBERS);
```

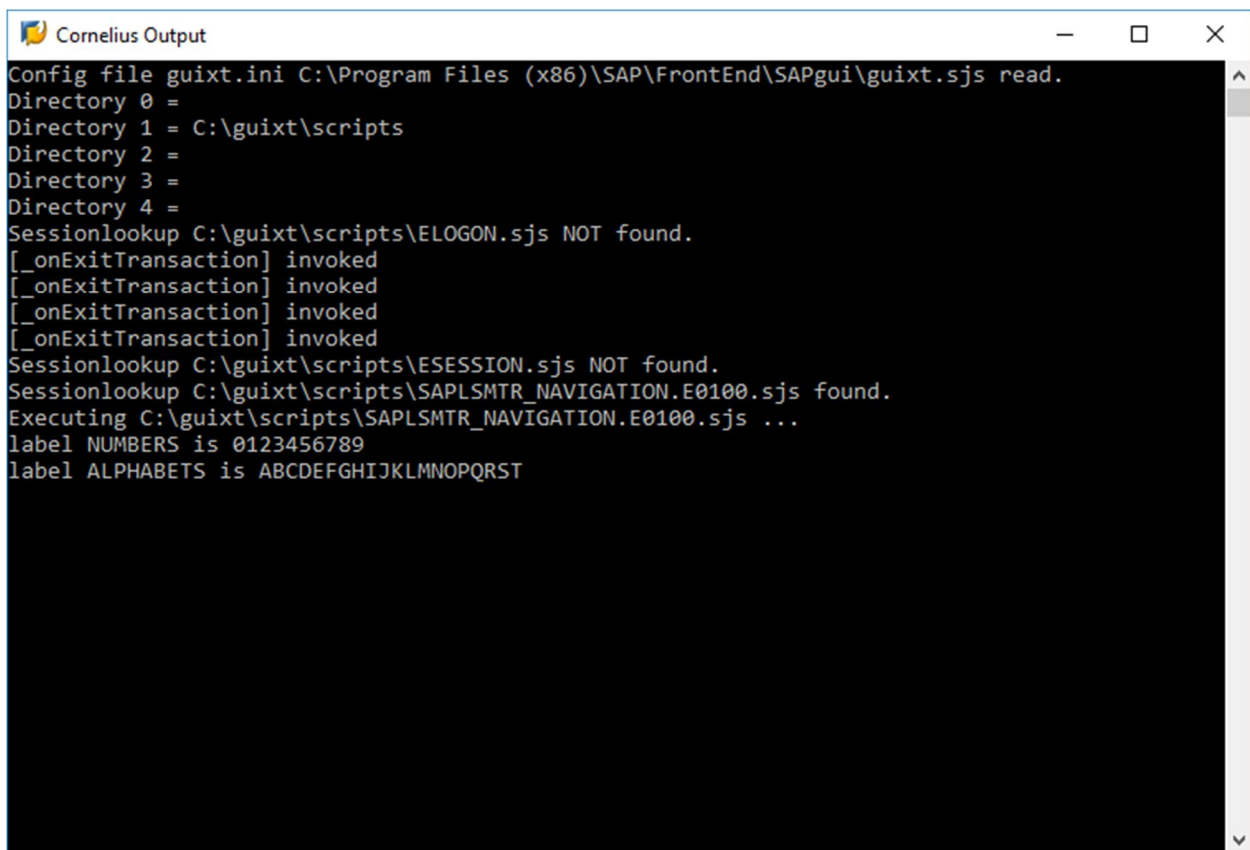

```
println("label ALPHABETS is "+elementArr.ALPHABETS);
```

You can see output on Cornelius window.

'elementArr.NUMBERS' as "0123456789"

'elementArr.ALPHABET' as "ABCDEFGHJKLMNOPQRST"

Cornelius Output

A screenshot of a window titled "Cornelius Output". The window has a standard Windows title bar with minimize, maximize, and close buttons. The content area is black with white text. The text shows the execution of a script, including directory listings, session lookups, and the final output of two labels.

```
